Topic: Agroforestry and the Environment

Subtopic: Climate Change (adaptation & mitigation)

Keywords: crop-livestock-forestry systems, nutrient flows, sustainability assessment tools, circularity scenarios

Type of presentation (oral or poster): Poster

Abstract

Specialization and the often resulting spatial separation of crop, livestock, and forestry production systems lead to loss of biodiversity and contribute to climate change. Integrating or combining crop, livestock, and forestry offer numerous opportunities to reduce the environmental impacts of agricultural production systems. Circular systems have been proposed to increase the efficiency of resource use, especially for scarce nutrients, and to use them more sustainably than conventional systems.

Therefore, the project SENSE aims to contribute to the study of integrated systems to gain a solid knowledge on the environmental impact of circular agroforestry systems (livestock-agroforestry, crop-agroforestry, and livestock-crop-agroforestry). In addition to the European partners of this project (Germany, Netherlands, United Kingdom and Italy), the expertise of more than 20 years of intensive research on these kinds of systems from the partners from South America (Argentina, Brazil and Uruguay) will be provided. Objectives in this project are to further develop indicators for effective quantification of the status of circularity, near real time measurements of greenhouse gas (GHG) emissions and prediction of emissions and nutrient fluxes through modelling. In order to assess the impacts of climate compatible management measures in a system-oriented way, multidimensional sustainability assessments with different tools (SMART, RISE, TAPE) will be carried out (Hani et al. 2003; Schader et al. 2016; Mottet et al. 2020).

The project activities will be based on case studies of farms and experimental sites of the different participating project countries. The core is formed by benchmark farms where the objectives (indicators for circularity, GHG emission, modelling, sustainability assessment tools) will be applied. The nutrient fluxes and GHG emissions of these farms, as well as trade-offs of further societal demands and ecosystem services, will be recorded and optimized. In a second group of farms (participatory), a scenario-based approach will be used to compare them according to their potential of reducing GHG emissions and investigate farmer acceptance of management practices to increase circularity. Leveraging information from individual farms and involving farmers at multiple levels and times during the whole activities will be crucial to the outcome of our project.

Our project will therefore address, among others, the questions which circular activities in integrated (crop, livestock, and forestry) systems lead to potential GHG reductions at the farm level, what are the externalities that determine the extent of circularity at the farm level, and what are the impacts of circularity measures in crop, livestock, and forestry systems on the SDG target 13 "Climate Action" and on other major challenges, such as biodiversity and appropriate incomes for farmers. The SENSE project will contribute to the European Union's net zero emissions target, the European Farm to Fork strategy and to the cross-cutting actions of the European Circular Economy Action Plan (Montanarella and Panagos 2021). Circularity is considered a prerequisite for climate neutrality, but has potentially negative impacts on other major societal challenges. We will provide guidance for informed decisions on circularity at the farm level, considering trade-offs with other sustainability goals.
